

YIELD OF CHICKPEAS SOWN AT DIFFERENT TIMES¹

RAMON IVO SOARES AVELAR^{2*}, CÂNDIDO ALVES DA COSTA², FERNANDO DA SILVA ROCHA², NELSON LICÍNIO CAMPOS DE OLIVEIRA³, WARLEY MARCOS NASCIMENTO⁴

ABSTRACT – In Brazil, studies on chickpeas (*Cicer arietinum* L.) have demonstrated the high productive potential of this crop, especially in the Cerrado areas of Cristalina, GO, and Brasília, DF. Due to dry winter climatic conditions, the North of Minas Gerais may be very suitable for the production of this crop. However, more information on chickpea sowing dates is needed. Therefore, the objective of the present study was to evaluate different chickpea sowing times in two municipalities of Minas Gerais State in Brazil: Montes Claros and Januária. The experiment was carried out in a randomized block design, comprising three sowing dates (12 May, 23 June, and 22 July, 2015), and seven replications. The cultivar used was BRS Aleppo, and the chickpeas were harvested 121 days after sowing. The variables evaluated included plant height, productivity, number of pods with one grain, and number of pods with two grains. The data were submitted to analysis of variance, and joint analysis of the experiments was performed. The highest yields were obtained when chickpeas were sown in May in Montes Claros, with a yield of 5.3 t ha⁻¹. In Januária, chickpeas sown in May and June produced yields greater than 3.0 t ha⁻¹. The plants sown in July, considered late for planting, were harvested during the rainy season, which compromised the quality and yield of the grains. In addition, maximum temperatures above 30°C were recorded from September onwards in both locations, which also resulted in a reduction in the number of grains per plant. Thus, this sowing season is not recommended in the studied region.

Keywords: *Cicer arietinum*. *Leguminosae*. Winter crops. BRS Aleppo.

PRODUTIVIDADE DO GRÃO-DE-BICO EM DIFERENTES ÉPOCAS DE SEMEADURA

RESUMO – Trabalhos realizados com a cultura do grão-de-bico (*Cicer arietinum* L.) no Brasil evidenciam elevado potencial produtivo desta espécie, especialmente nas áreas de cerrado de Cristalina, GO e Brasília, DF. O Norte de Minas Gerais possui potencial produtivo por apresentar condições de inverno seco. Entretanto, mais informações sobre épocas de semeadura do grão-de-bico precisam ser levantadas. Dessa forma, objetivou-se avaliar a melhor época de semeadura do grão-de-bico nos municípios de Montes Claros e Januária, MG. O experimento foi realizado em blocos completos ao acaso, compreendendo três épocas de semeadura (12/Maio, 23/Junho, 22/Julho) e sete repetições. A cultivar utilizada foi BRS Aleppo e a colheita realizada aos 121 dias após a semeadura. Foram variáveis analisadas foram: altura de plantas, produtividade, número de vagens com um grão e número de vagens com dois grãos. Os dados foram submetidos à análise de variância sendo realizada a análise conjunta dos experimentos. Maiores produtividades foram obtidas em Montes Claros na semeadura realizada no mês de maio com produtividade de 5,3 t ha⁻¹, e em Januária nas semeaduras de Maio e Junho, com produtividades superiores a 3,0 t ha⁻¹. Por ser tardia, verificou-se que para a semeadura no mês de Julho ocorreu chuvas no período de colheita, comprometendo a qualidade e rendimento dos grãos. Além disso, foram registradas temperaturas máximas superiores a 30 °C a partir do mês de Setembro nas duas localidades, o que resultou também na redução do número de grãos por planta. Assim, essa época de semeadura não é recomendada nos municípios estudados.

Palavras-chave: *Cicer arietinum*. *Leguminosae*. Cultivo de inverno. BRS Aleppo.

INTRODUCTION

The chickpea (*Cicer arietinum* L.) is an important legume, known for its nutritional characteristics. The chickpea plays a key role in feeding millions of people around the world, especially in India, which is the largest producer and consumer (JUKANTI et al., 2012; RAO et al., 2010). It is the second most cultivated legume in the world, with a great variety of genotypes divided into two groups according to the size of the seeds, including the Kabuli (large) and Desi (small) groups (VARSHNEY et al., 2013a).

Low productivity of chickpeas has been observed in many countries, with averages of less than 1.2 t ha⁻¹ (FAO, 2018), due mainly to water stress conditions, salinity, and heat (VARSHNEY et al., 2013b; KHAMSSI et al., 2011; MAFAKHERI et al., 2010; GUNES et al., 2008). Most of the crops in the world are farmed with limited technology (ABATE; ORR, 2012), and in rain-fed land, taking advantage of the residual water from the rainy season (ALI, 2017). However, some countries, including Israel (6.04 t ha⁻¹ in 2012), China (5.2 t ha⁻¹ in 2015), and Moldova (3.9 t ha⁻¹ in 2016) have achieved high chickpea yields.

The cultivation of chickpeas is still not widespread in Brazil, and the production is insufficient to serve the consumer market, which depends on imports. Current imports are approximately 8,000 tons/year, which cost the country nearly \$9 million (NASCIMENTO et al., 2016).

The cultivation of chickpeas is recommended in the spring/summer in milder climates, or in winter in tropical climates (NASCIMENTO et al., 2016). Although considered a cold weather legume, the chickpea adapts very well to tropical regions, where it develops well and has good productivity. In addition, chickpeas are tolerant to water deficits (BRAGA; VIEIRA; VIEIRA, 1997).

In the reproductive period of chickpeas, mild temperatures and dry conditions favor the culture, since these conditions help avoid floral abortion and result in a better formation of pods. In general, the highest yields are obtained at altitudes above 600 m, with night temperatures below 15 °C (NASCIMENTO et al., 2016).

Studies show that the Northern Region of Minas Gerais has a high potential for cultivation of chickpeas. Hoskem et al. (2017) evaluated the production and quality of seeds of chickpeas (Cicero cultivar) in two locations in the city of Montes Claros - MG, and found that the best time for sowing is in the month of June, with yields of 3.2 t ha⁻¹ and 3.9 t ha⁻¹, respectively. A study by Vieira, Resende and Castro (1999), in Janaúba, MG, using the Leopoldina and IAC Moroco cultivars reported productivity greater than 3 t ha⁻¹.

Recently, Embrapa Hortaliças launched the

BRS Aleppo cultivar, which is more productive, and tolerant to diseases caused by fungi. This cultivar was introduced in Brazil in 2010, and participated in several trials in the Federal District (DF) and Goiás (GO) before its release in the year 2013, including in irrigated areas of commercial production (NASCIMENTO et al., 2014). The results indicated that the Aleppo cultivar had productive performances than the Cicero cultivar. The yield was on average 3.0 t ha⁻¹, which is considered high, when compared to the Cicero cultivar, which had an average yield of 0.94 t ha⁻¹ (ARTIAGA et al., 2015).

However, further studies are needed to determine the best time for sowing chickpeas for maximum efficiency and expansion of production areas. Therefore, this study aimed to evaluate the best time to sow chickpeas in two municipalities in the North of Minas Gerais.

MATERIAL AND METHODS

The experiments were performed between May and November of 2015. Studies were conducted in the municipalities of Montes Claros - MG, Brazil (16° 40' 56" S, 43° 50' 24" W, at an altitude of 646 m) in the experimental area of the Agricultural Sciences Institute of UFMG, and in Janaúria - MG (15° 26' 47" S, 44° 22' 05" W and a height of 474 m), at the Federal Institute of Technology North of Minas Gerais - IFNMG. The climate classification of municipalities is KöppenAw, located in micro-regions in the North of Minas Gerais.

The chemical and physical characteristics of soils of the experimental areas in Montes Claros - MG and Janaúria - MG are presented in Table 1.

Data on precipitation, maximum and minimum daily temperatures, collected by the National Institute of Meteorology (BRASIL, 2016) during the experiments, at the two sites, are presented in Table 2.

The statistical design used was randomized blocks, and chickpeas were sown at three different times (May 12th, June 21st, and July 22nd, 2015), and in two locations (Montes Claros - MG and Janaúria - MG), with seven replicates.

Each farmed plot of chickpeas (BRS Aleppo) was composed of four rows of five meters in length, spaced 0.50 m apart. Before planting, the seeds were treated with fungicide and insecticide phenylurea (systemic, contact and ingestion of groups: neonicotinoid and methylcarbamate of oxime), respectively. Ten plants were seeded per meter, which corresponded to a density of 200,000 plants ha⁻¹. The experimental plots consisted of 1.0 m² in the two central rows, and the rest was considered as a perimeter. The BRS Aleppo plants have a semi-erect profile, an average height of 66 cm, and three to four branches per plant. The cycle is around 120 days

after emergence (DAE), and the seeds are 8 to 9.5 mm of diameter (NASCIMENTO et al., 2014).

The fertilization and irrigation followed the recommendations of Nascimento et al. (2016), considering Cerrado soils of low fertility. Fertilizing

consisted of 400 kg ha⁻¹ of the formula 4-30-16 in crops and 60 kg ha⁻¹ of nitrogen (N) in coverage, between 40 and 50 days after sowing, prior to the beginning of flowering. Irrigations were carried out using micro-aspersion.

Table 1. Chemical and physical characterization of soils of the experimental areas in the municipalities of Montes Claros and Januária, Minas Gerais.

Local	pH	Chemical Characterization								
		P (mg dm ⁻³)	K	Al	H+Al (cmolc dm ⁻³)	Ca	Mg	OM (dag kg ⁻¹)	rem-P (mgL ⁻¹)	V (%)
Montes Claros	6.8	3.89	249	0.0	1.42	6.4	1.6	3.39	31.79	86
Januária	7.1	255	134	0.0	1.08	2.8	1.2	3.39	37.55	80
Local	Physical Characterization					Textural Class				
	Clay	Silt	Fine Sand (dag kg ⁻¹)	Coarse Sand						
Montes Claros	28.0	40.0	20.0	12.0	Medium					
Januária	6.0	8.0	51.40	34.6	Sandy					

* OM = organic matter, rem-P = remaining phosphorus.

Table 2. Minimum, average, and maximum temperatures, relative humidity and precipitation during the period the experiments were conducted, in the municipalities of Montes Claros and Januária, MG.

Climatic characteristics	Month						
	May	June	July	August	September	October	November
	Montes Claros						
T°C Maximum	29.3	29.0	28.8	29.9	35.3	35.5	35.2
T°C Average	23.5	22.6	22.5	23.2	27.8	28.7	29.0
T°C Minimum	17.7	16.3	16.1	16.5	20.3	21.8	22.9
Precipitation (mm)	5.4	0.0	0.0	1.1	0.2	3.0	103.2
Air humidity (%)	62.9	55.2	54.5	48.1	38.5	41.0	52.7
	Januária						
T°C Maximum	25.8	25.5	25.5	26.3	30.6	31.4	31.0
T°C Average	23.2	22.1	22.0	22.1	25.0	25.9	26.6
T°C Minimum	20.5	18.8	18.4	17.9	19.4	20.4	22.1
Precipitation (mm)	19.0	0.0	0.2	0.0	0.2	3.0	0.0
Air humidity (%)	61.1	51.8	49.6	42.7	33.0	35.0	47.4

Hoeing was conducted weekly for weed control, until the closure of the area at 30 DAE. After the beginning of flowering, insecticide was applied three times. The first two times were with a systemic insecticide (neonicotinoid and pyrethroid), and the third with a contact insecticide (pyrethroid; the basis of deltamethrin [2.5%]) for the control of caterpillars (*Heliothis virescens*), with intervals of 15 days between applications of insecticides.

Irrigation was suspended at 100 days after sowing, when the plants were coloring, indicating a change in stage of senescence, as recommended by Nascimento et al. (2016). The chickpeas were harvested 121 days after sowing.

The variables analyzed were the heights of the plants, yield, number of pods with one grain, and the number of pods with two grains. The data on the number of pods with one grain and the number of pods with two grains underwent a square root

transformation (\sqrt{x}), although we present the original values. The data were subjected to analysis of variance (ANOVA) using joint analysis of the experiments, and averages were compared by Tukey test at 5% probability. The correlations between variables were analyzed by the method of Pearson at 5% probability. All data analysis was conducted with R software (v. 3.2.2).

RESULTS AND DISCUSSION

The number of pods (with one and two grains) and the yield of the chickpeas were affected by the interaction between time of sowing and location of the experiment ($p < 0.05$). The height of plants was affected only by the sowing season (Table 3).

There are few records on the productive characteristics of the BRS Aleppo cultivar. The highest productivity was achieved when chickpeas were sown in May in Montes Claros – MG, exceeding 5.0 t ha^{-1} (Figure 1). For chickpea sown in June, there was no statistical difference between sites, with an average yield of 3.6 t ha^{-1} . The biggest

difference between sites was when chickpeas were sown in July, with a fairly drastic reduction in productivity in the municipality of Januária - MG. The highest productivity was achieved when chickpeas were sown in May in Montes Claros - MG.

Table 3. Summary of the joint analysis of variance of the experiments, for variables of production of chickpeas in relation to times of sowing, in the municipalities of Montes Claros and Januária, Minas Gerais.

Figure 1. The yield of chickpeas sown at different sowing times in the municipalities of Montes Claros and Januária, Minas Gerais.

In trials conducted during four years in areas of Cerrado of Distrito Federal and Goiás, Nascimento et al. (2014) observed yields of the BRS Aleppo cultivar ranged from 2.51 t ha^{-1} to 3.52 t ha^{-1} . In the same period, the Cicero cultivar produced yields from 0.44 t ha^{-1} to 1.27 t ha^{-1} .

Under conditions similar to those in the present study, Hoskem et al. (2017) tested the Cicero cultivar at three different sowing times (May 22nd, June 20th, and July 26th), and reported yields averaging 2.72 t ha^{-1} , with the best result obtained when chickpeas were sown in the month of June,

with yields close to 3 t ha^{-1} .

Evaluating the chickpea cultivars in Coimbra, a municipality of Zona da Mata-MG, at an altitude of 800 m, in 1993 and 1994, Braga, Vieira and Vieira (1997), reported yields from 1.58 to 1.62 t ha^{-1} with the IAC Morocco cultivar, yields from 2.04 to 2.35 t ha^{-1} with the ICCV-3 (Leopoldina) cultivar, and yields from 1.03 to 1.46 t ha^{-1} with the Cicero cultivar. In a study by Vieira, Rezende and Castro (1999), in the Zona da Mata and in the North of Minas, the IAC Morocco cultivar, grown in the municipality of Coimbra (micro-region of

Viçosa-MG), provided a yield of 1.79 t ha⁻¹. In Leopoldina-MG and Janaúba-MG, the Leopoldina and IAC Morocco cultivars reached yields greater than 2 t ha⁻¹ and 3 t ha⁻¹, respectively. The Cicero cultivar did not produce yields greater than 1.80 t ha⁻¹.

A study by Artiaga et al. (2015), using 15 chickpea genotypes in non-irrigated land cultivation in the Midwest region of Brazil during three seasons of planting, reported yields up to 1.34 t ha⁻¹. For the IAC Morocco and Cicero cultivars, the maximum

yield was 0.34 t ha⁻¹ when soybeans were sown the month of March, and 0.62 t ha⁻¹ when chickpeas were sown in the month of January, respectively.

Regarding the height of plants, greater values were found in chickpeas sown in May, and heights were reduced in the chickpeas sown in July (Table 4). According to NASCIMENTO et al. (2014), the height of the plants of the cultivar BRS Aleppo is approximately 66 cm, which is similar to the values obtained in this study for the chickpeas sown in May and June.

Table 4. Plant height, number of pods with one grain, and number of pods with two grains of chickpeas in relation to sowing times in the municipalities of Montes Claros and Janaúria, Minas Gerais.

Time of sowing	Height (cm)	Locals			
		Montes Claros		Janaúria	
		Number of pods with 1 grain (plant)		Number of pods with 2 grains (plant)	
May 12	64.7 a	9.7*(85.9**) Aa	6.9 (41.9) Ba	3.0 (6.4**)Ba	3.9 (11.6)Aa
June 23	61.2 ab	5.4 (25) Bc	7.2 (44.8) Aa	1.6 (1.4) Bb	2.9 (6.5) Ab
July 22	51.0 b	7.5 (49.3) Ab	3.7 (10.5)Bb	3.04 (6.6) Aa	1.9 (2.1) Bc
CV (%)	12.3		11.5		15.4

Averages followed by the same uppercase letter in a line do not differ significantly, based on analysis using the F-test, and averages followed by the same lowercase letters in a column do not differ significantly based on analysis using the Turkey test at 5% probability.

*Data was transformed by $(\sqrt{x} + 0.5)$ ** Non-transformed data.

Artiaga et al. (2015), assessed chickpea genotypes sown in non-irrigated land in the Midwest of Brazil from January to July, and found heights for the Cicero cultivar ranging from 33 to 57 cm, and heights for the IAC Morocco cultivar ranging from 45 to 63 cm. Hoskem et al. (2017), using the Cicero cultivar, found the highest values for plant height (52 cm) in the municipality of Montes Claros-MG when chickpeas were sown in May.

Considering cultures with indeterminate growth habits (GAUR et al., 2010), plants of greater height, in general, result in higher production, taking into consideration their normal development. This is related to the cycle of cultivars. For example, the Cicero cultivar has a cycle of approximately 110 days, while that of the BRS Aleppo cultivar is 120 days.

In addition, temperature and air humidity affect production. Temperatures below 10 °C and above 30 °C are detrimental to the development of the chickpea cultivars, especially in the reproductive phase, and may cause abortion of flower buds and affect the formation of pods (NASCIMENTO et al., 2016). Under conditions of temperatures above the optimum for the cultivar, its cycle is shortened, resulting on premature senescence, and the production and viability of pollen grains are reduced (KUMAR et al., 2013), which negatively affects the production of the cultivar (DEVARSIVATHAM et al., 2012).

The number of pods with one grain (Table 4)

was higher when chickpeas were sown in May in Montes Claros, and the number of pods with two grains (Table 4) was higher when chickpeas were sown in May in Janaúria.

During the experimental period, maximum temperatures over 30° C were recorded from the month of September onwards in both locations, which resulted in the reduction of the number of grains (Table 2). The plants that were sown in May were at the end of the cycle, and, therefore, the high temperatures did not harm their development.

The yield and the number of pods with one grain were highly positively correlated (Table 5). The pods that produce just one grain, found in greater numbers, feature larger grain weight, compared to grains produced in greater numbers per pod. There was a weak correlation ($r = 0.39$) between productivity and plant height. Artiaga et al. (2015) and Biabani et al. (2011) found a positive correlation between such variables, reporting values of $r = 0.61$ and $r = 0.78$. Samad, Sarker and Deb (2014) observed a negative correlation between plant height at maximum flowering and grain number per plant.

In this study, it can be inferred that the tallest plants had a higher vegetative development, without producing more grains.

The number of pods with one grain was also correlated with the number of pods with two grains, indicating that when production increases, there is also a greater number of pods with two grains.

Table 5. Simple Pearson correlation between the variables evaluated regarding the production of chickpeas of the BRS Aleppo cultivar at different sowing times in the municipalities of Montes Claros and Januária, Minas Gerais.

	HGT	NP1	NP2
YLD	0.39*	0.92**	0.34 ^{ns}
HGT		0.42*	0.22 ^{ns}
NP1			0.37*

** = 1% probability, * = 5% probability, Pearson's correlation.

YLD = yield; HGT = height of plants; NP1 = number of pods with one grain (plant); NP2 = number of pods with two grains (plant).

CONCLUSION

The best time for the sowing of chickpeas in the municipality of Montes Claros - MG was in May, with a yield of 5.3 t ha⁻¹. In the municipality of Januária - MG, the best times for sowing chickpeas were the months of May and June, with a yield exceeding 3 t ha⁻¹.
