AGRADECIMENTOS

Fazer um mestrado sempre me pareceu uma caminhada longa e exigente, mas que sempre disse a mim mesma que faria. Fazer um mestrado, em meio a uma pandemia, requereu muito a presença (mesmo que virtual) de pessoas que sempre me apoiaram incondicionalmente e me ensinaram muito neste processo.

Minha mãe, agradeço por ser meu maior sustento e apoiadora dos meus sonhos. Pai e Gabriel, elos da minha família que me ajudam a não me cobrar tanto e levar uma vida mais leve. Pedro, obrigada por ser minha companhia, ser o ouvido que me escuta e apoia, sempre presente e trilhando juntos pela vida.

Professor Felipe, agradeço por todos os ensinamentos passados, de forma direta e leve. Você me ofereceu muitas ferramentas para que eu buscassem o conhecimento com meus próprios olhos. Obrigada por valorizar tudo o que levei até você e me incentivar a buscar sempre mais.

Colegas da pós-graduação, obrigada por compartilharem a jornada! Nossos surtos compartilhados valeram a pena, em especial Rapha e Carol. Sissa e Gabi, obrigada por me acolherem e me oferecerem conselhos preciosos. Lucas e Ana Luisa, obrigada pela valiosa contribuição neste trabalho e por me instigarem a ensinar.

Amigas de Ipatinga (Anna, Ana, Lívia, Let, Lô, Giane) e da Odonto (Laissa, Lígia e Fê), obrigada por estarem sempre comigo, por serem meu alívio nos momentos necessários e apoio para quando a energia estava baixa.

Agradeço aos mestres que muito me ensinaram, que me ouviram, me corrigiram e serviram de exemplo.

A todos que contribuíram direta ou indiretamente nesses anos de mestrado, o meu muito obrigada!

“Não é a montanha que conquistamos, mas a nós mesmos”

Edmund Hillary

RESUMO

Introdução: linfomas e leucemias são neoplasias linfohematopoiéticas que podem acometer região oral e maxilofacial, incluindo os ossos gnáticos, com aspectos imaginológicos semelhantes a outras neoplasias e processos reativos.

Objetivo: Investigar os aspectos radiográficos de linfomas e leucemias em maxila e mandíbula. **Metodologia:** Uma revisão sistemática foi realizada nas bases eletrônicas Pubmed, Web of Science e Scopus utilizando estratégias específicas de busca. Os critérios de inclusão compreenderam artigos que forneceram imagens do tipo periapical, panorâmica ou tomografia computadorizada (TC) dos casos individualizados e o diagnóstico de leucemia/linfoma pôde ser confirmado por imunoistoquímica. Três avaliadores analisaram e descreveram individualmente as imagens e a qualidade dos exames radiográficos. **Resultados:** Do total de 1079 artigos escaneados, foram selecionados 129 casos contendo 88 tomografias computadorizadas, 77 panorâmicas e 26 exames periapicais, a maioria (54%) classificados com uma qualidade excelente. O linfoma difuso de grandes células B, sem outras especificações (LDGCB SOE) (32,6%), linfoma de Burkitt (17,1%), infiltrado leucêmico (14,7%), linfoma plasmablástico (7,8%) e linfoma de células NK/T (5,4%) foram os subtipos mais comuns. Os dentes envolvidos apresentaram mobilidade em 37,2% dos casos e um diagnóstico primário de doenças infecciosa/inflamatória foi considerado em 49,2% dos pacientes. A maioria dos casos eram radiolúcidos em exames periapical e panorâmico e a TC estava disponível em 76% dos casos, com um aspecto hipodenso e de bordas mal definidas. Reação periosteal foi pouco comum (4,7%). **Conclusões:** linfomas/leucemia com destruição dos ossos gnáticos usualmente representam subtipos de alto grau e raramente apresentam reação periosteal na imagem radiográfica.

Palavras-chave: Linfoma, Leucemia, Maxila, Mandíbula, Ossos maxilares, Radiografia

ABSTRACT

Radiological aspects of lymphomas and leukemias affecting the jaws

Objective: To investigate the radiographic features of lymphomas and leukemias in the jaws. Study Design: A systematic review was carried out in the electronic databases Pubmed, Web of Science and Scopus using specific search strategies. Inclusion criteria comprised articles that provided periapical, panoramic or computed tomography (CT) images for individual cases and diagnoses of lymphoma/leukemia confirmed by immunohistochemistry. Three experts evaluated and described individually the images and the quality of the radiographic exams. Results: From 1079 reports screened, 129 cases containing 88 tomographic, 77 panoramic and 26 periapical exams were selected, most of them classified as excellent (54%). Diffuse large B-cell lymphomas NOS (DLBCL), Burkitt lymphoma, leukemic infiltration, T/NK-cell lymphoma and plasmablastic lymphoma were the most common subtypes. Involved teeth presented mobility in 37.2% of the cases and a provisional diagnosis of inflammatory/infectious dental disease was considered in 49.2% of the patients. Most cases were radiolucent in plain exams and conventional CT exams were available for 76% of the cases, with hypodense aspect and ill-defined borders. Periosteal reactions were uncommon. Conclusion: Lymphoma/leukemia with gnathic bone destruction are usually of high-grade subtypes and rarely present periosteal reactions.

Keywords: lymphoma, leukemia, gnathic bones, imaging, periapical, panoramic, computed tomography

1 CONSIDERAÇÕES INICIAIS

As neoplasias de origem linfohematopoiéticas são denominadas leucemias e linfomas. Leucemia é o termo empregado às diversas desordens malignas que se apresentam com um número aumentado de leucócitos anormais no sangue e/ou na medula óssea, enquanto que os linfomas representam neoplasias de células linfoïdes imaturas ou maduras, podendo ser da linhagem B, T ou NK, que deixam de exercer suas funções fisiológicas normais de defesa imunológica e exibem um crescimento descontrolado, principalmente em linfonodos, mas também em regiões extra-nodais e que se apresentam clinicamente como crescimentos sólidos (JULIUSSON; HOUGH, 2016; SWERDLOW SH *et al.*, 2017).

Os linfomas e leucemias representam um importante grupo de lesões que podem acometer a cavidade oral e as estruturas anatômicas adjacentes, incluindo os ossos maxilares, os quais podem ser afetados de forma primária por diferentes subtipos de linfomas e leucemias, ou secundariamente por meio da extensão destas lesões em direção à maxila e mandíbula.

O presente estudo representa uma continuação da linha de trabalho que objetiva melhor compreender as manifestações clínicas, microscópicas e imunoistoquímicas dos principais subtipos de linfomas orais e maxilofaciais, cujos resultados tem sido continuamente reportados na literatura por nosso grupo de trabalho ao longo dos últimos anos, na forma de séries de casos organizadas inicialmente em função dos subtipos histológicos definidos pela Organização Mundial da Saúde (DE ARRUDA *et al.*, 2021; DE SENA *et al.*, 2021) e posteriormente em função de algumas topografias anatômicas mais específicas como as glândulas salivares maiores (ARAUJO *et al.*, 2022). Ressalta-se ainda, que temos desenvolvido estudos laboratoriais que buscam avaliar as bases moleculares de alguns destes linfomas orais, com destaque para o linfoma difuso de grandes células B sem outra especificação e o linfoma plasmablástico, dois principais subtipos de linfomas em cavidade oral, cujos resultados iniciais estão sendo preparados para divulgação.

Desta forma, buscamos nesta dissertação de mestrado contribuir com a expansão desta linha de pesquisa por meio da investigação do padrão radiográfico/imaginológico dos linfomas e leucemias quando do acometimento dos ossos gnáticos. Muito pouco tem sido discutido até então sobre este assunto e acreditamos que uma análise dos casos já relatados na literatura por meio de uma

metodologia sistematizada de revisão poderá contribuir para que estomatologistas, radiologistas e patologistas orais possam aperfeiçoar suas condutas diagnósticas no contexto de pacientes afetados por estas neoplasias malignas. Além disso, entendemos que os resultados obtidos com este projeto poderão ser utilizados como referência para que novos estudos originais avaliem de forma mais detalhada os aspectos radiográficos/imaginológicos de linfomas e leucemias em maxila e mandíbula.

2 REVISÃO DE LITERATURA

O diagnóstico e classificação de leucemias e linfomas é complexo e necessita de análises microscópicas, reações imunoistoquímicas, avaliação de translocações genéticas e outros eventos moleculares, investigação da presença de agentes virais como o vírus Epstein-Barr (EBV) e o vírus da imunodeficiência humana (HIV), além de uma forte correlação com achados clínicos. Para tanto, os exames de imagem se mostram fundamentais para compreender o tamanho das lesões e os sítios que elas acometem, permitindo assim realizar um estadiamento da doença de forma mais acurada, além de contribuir com o seguimento clínico pós-terapêutico dos pacientes afetados (MACDONALD; MARTIN; SAVAGE, 2021; SWERDLOW SH *et al.*, 2017).

As leucemias podem ser classificadas de acordo com o tipo predominante de células, em mielocítica ou linfocítica, pelo estágio de diferenciação das células e considerando também o curso clínico da doença (aguda ou crônica). Elas irão acometer tanto pacientes infantis (entre um e quatro anos de vida) quanto adultos (na faixa dos 40 anos) e pacientes idosos (entre 60 e 70 anos). Além das manifestações sistêmicas, as manifestações orais incluem aumento de volume e sangramento gengival, ulcerações orais, petequias e perda de coloração da mucosa. Estas são resultado tanto da infiltração de células leucêmicas, constituindo uma manifestação primária, quanto um reflexo das alterações sistêmicas (secundárias) (FRANCISCONI *et al.*, 2016; JULIUSSON; HOUGH, 2016). Estudos recentes demonstram que os sintomas orais são mais frequentes em leucemias agudas, podendo representar sinais suspeitos para o diagnóstico inicial da doença. Os sintomas mais comuns são o sangramento gengival e aumento de volume gengival (DE SENA *et al.*, 2021; WATSON *et al.*, 2018).

Os linfomas são originados de linfócitos, podendo ser divididos em linfoma de Hodgkin (LH) e linfoma não-Hodgkin (LNH) em função das suas características microscópicas que repercutem em diferenças biológicas e clínicas. Os LH são menos comuns e estão virtualmente restritos aos linfonodos. Os LNH podem se manifestar em sítios extra-nodais em aproximadamente 40% dos casos e compõem uma grande lista de subtipos reconhecidos pela Organização Mundial de Saúde baseado em seus achados microscópicos, características clínicas, imunofenotipagem e eventos

genéticos (KOLOKOTRONIS *et al.*, 2005; KUSUKE; CUSTÓDIO; DE SOUSA, 2019; SWERDLOW SH *et al.*, 2017). Em 2020, estima-se que 544.352 pacientes em todo o mundo foram diagnosticados com LNH e 259.793 faleceram em decorrência da doença (SUNG *et al.*, 2021). Em geral, os linfomas constituem o segundo grupo de malignidades mais comuns na região de cabeça e pescoço, inferior apenas ao grupo de malignidades de origem epitelial. É notável o linfoma difuso de grandes células B (LDGCB) como variante predominante de ocorrência em região oral e maxilofacial, seguido de outros subtipos de linfomas de células B de alto grau, como o linfoma plasmablástico e o linfoma de Burkitt, e em menor ocorrência os de baixo grau, como o linfoma folicular e o linfoma da zona marginal do tecido linfoide associado a mucosa (MALT). Os linfomas de células T correspondem a aproximadamente um terço dos subtipos que afetam a região oral, sendo o linfoma de células NK/T extranodal, tipo nasal (ECTNK-TN) o mais comum. As áreas mais acometidas são a região alveolar da gengiva e o palato, apesar de a região do anel de Waldeyer (que representa a coleção de tecido linfoide circundante à鼻e orofaringe) ser o sítio mais comum de acometimento de linfomas em cabeça e pescoço (CABEÇADAS *et al.*, 2019; DE ARRUDA *et al.*, 2021; KUSUKE; CUSTÓDIO; DE SOUSA, 2019).

Aproximadamente um terço a metade dos linfomas e leucemias orais acometem os ossos maxilares e mostram alterações radiográficas significativas, podendo acometer também regiões anatômicas vizinhas como fossa nasal e seios maxilares (DE SENA *et al.*, 2021; EISENBUD *et al.*, 1984; KEMP *et al.*, 2008; MACDONALD; MARTIN; SAVAGE, 2021; VAN DER WAAL *et al.*, 2005). Em relação às características clínicas dos linfomas em maxila e mandíbula, nota-se que o aumento de volume é o sinal mais relatado em um primeiro momento, podendo haver também dor e parestesia. A parestesia é um sintoma importante em lesões que afetam mandíbula, pela anatomia do canal mandibular na região, mas também merece atenção em lesões maxilares, pela proximidade com o nervo infra-orbital, e ambos são relatados na literatura. Nos casos descritos na literatura, os pacientes notaram o aparecimento da lesão apenas um a dois meses antes de buscarem atendimento diagnóstico especializado e as primeiras hipóteses diagnósticas consideradas foram infecção dentária e carcinoma de células escamosas (LIU *et al.*, 2022; MACDONALD; LIM, 2018; MORTAZAVI *et al.*, 2020).

A literatura para análise de linfomas e leucemias acometendo os ossos maxilares, até o presente momento, é majoritariamente baseada em relatos de casos.

Alguns poucos estudos, entretanto, buscaram descrever as características radiográficas do linfoma plasmablástico (NEL *et al.*, 2021) e revisaram as características destas lesões quando presentes na forma de imagens periapicais (MORTAZAVI *et al.*, 2020). Além disso, séries de casos de alguns subtipos específicos demonstraram que o linfoma de células NK/T extranodal, tipo nasal (ECTNK-TN) está usualmente associado com a presença de imagens osteolíticas na região central do palato/maxila, ao passo que pacientes afetados por linfoma de Burkitt com frequência exibem uma destruição significativa do rebordo alveolar que leva ao padrão conhecido por “dentes flutuantes” (LIU *et al.*, 2022; MACDONALD; MARTIN; SAVAGE, 2021).

As técnicas de aquisição de imagens evoluíram para o formato digital e tiveram seu acesso mais disseminado nos últimos anos, especialmente as tomografias computadorizadas de feixe cônicoo. Entretanto, uma melhor caracterização imaginológica de cada subtipo de linfoma ainda é escassa e necessária. A tomografia computadorizada por feixe cônicoo (TCFC) pode auxiliar o cirurgião-dentista a reconhecer se lesões que envolvem dentes não-vitais ou com raízes reabsorvidas em imagens convencionais teriam um aspecto sugestivo de lesões mais agressivas que possam sugerir uma natureza maligna ou inflamatória. Vale ressaltar, que os aspectos radiográficos de lesões malignas podem não receber adequada atenção se não associados a um aspecto clínico convencionalmente reconhecido como malignidade, como necrose e ulceração, que nem sempre estão presentes em manifestações orais de linfomas e leucemias (MACDONALD; LIM, 2018).

Alguns estudos que reuniram dados imaginológicos de LNH descrevem as lesões como osteolíticas, com bordas irregulares e mal definidas, densidade homogênea e envolta por massas de tecido mole (em exames de tomografias computadorizadas e ressonância magnética). Em mandíbula, as lesões se infiltram pelo longo eixo do osso, podendo estar acompanhadas por destruição da cortical ou aumento do diâmetro do canal mandibular. Os linfomas em maxila podem facilmente envolver os seios maxilares, palato duro, órbitas, cavidade nasal, fossa pterigopalatina e canal infraorbital, de forma que se torna difícil distinguir se a origem do linfoma é a região alveolar da maxila ou os seios maxilares, sendo agrupados como uma mesma entidade. Podem também ser multicéntricas, acometendo mais de uma região dos ossos gnáticos, vir acompanhados de linfadenopatia e a reação periosteal é raramente

encontrada. Por seu aspecto altamente destrutivo, quando acometem a região dos dentes, pode-se visualizar o aspecto de dentes flutuantes nas imagens, por ausência de suporte ósseo, podendo se assemelhar a doença periodontal ou lesão infecciosa (LIU *et al.*, 2022; MACDONALD; MARTIN; SAVAGE, 2021).

Em estudo focado nos aspectos radiológicos de pacientes com linfoma plasmablástico encontrou-se imagens semelhantes às descritas, osteolíticas e com margens mal definidas, porém observou-se prevalência pela região da maxila e seios maxilares. Este subtipo pode envolver um ou mais sítios e por ter forte associação com infecções por HIV e EBV, apresenta maior prevalência em homens, que são a população prevalente destas doenças (NEL *et al.*, 2022).

As manifestações orais de leucemias, quando atingem os ossos gnáticos, têm como principais características radiográficas a expansão da cortical do osso alveolar, áreas osteolíticas, aumento do espaço do ligamento periodontal e perda da lámina dura e moderada perda óssea angular nos dentes afetados com mobilidade (DE SENA *et al.*, 2021. QUISPE *et al.*, 2022).

Em uma primeira abordagem clínica e com exames complementares radiográficos, o diagnóstico diferencial e a escolha de conduta clínica deverão se basear na junção destes dados. Quando acometem região periapical dos dentes, lesões com as margens mal definidas, teste de sensibilidade positivo em dente acometido e mudança de posição dos dentes podem sugerir uma lesão neoplásica em detrimento de reação inflamatória (MORTAZAVI *et al.*, 2020). Lesões que acometem maxila e região sinonasal podem se assemelhar ao carcinoma de células escamosas (CCE). Radiograficamente, o CCE em geral demonstra um aspecto mais destrutivo das paredes dos seios maxilares, enquanto os LNH apresentam um crescimento mais permeativo, podendo ocasionar remodelação e esclerose óssea e geralmente mantém a integridade das paredes dos seios maxilares (KATO *et al.*, 2015; KIM *et al.*, 2018).

Por geralmente demonstrarem um crescimento rápido e sintomático, muitas vezes o cirurgião-dentista é o primeiro profissional procurado por esse paciente. Dessa forma se faz necessário que esse profissional esteja ciente dessa possibilidade diagnóstica e saiba diferenciá-la de outras entidades, como lesões reativas inflamatórias, utilizando os recursos diagnósticos disponíveis, sendo muitas vezes o

exame de imagem convencional (radiografias panorâmicas e periapicais) um dos principais e mais amplamente disponível (MACDONALD; LIM, 2018).

3 OBJETIVOS

3.1 Objetivo Geral

Descrever os aspectos radiográficos dos linfomas e leucemias nos ossos maxilares relatados na literatura.

3.2 Objetivos Específicos

- Avaliar os aspectos radiográficos dos diferentes tipos de linfoma e leucemias em maxila e mandíbula;
- Investigar as características radiográficas e tomográficas dos linfomas e leucemias em ossos maxilares em função de sua relação com os dentes adjacentes;
- Investigar as características radiográficas e tomográficas dos linfomas e leucemias em ossos maxilares em função de sua relação com a ocorrência de alterações periosteais;
- Analisar a qualidade das imagens radiográficas disponibilizadas nos artigos incluídos neste estudo.

4 METODOLOGIA EXPANDIDA

Esta revisão sistemática foi conduzida de acordo com as normas preconizadas pelo PRISMA (*Preferred Report Items for Systematic reviews and Meta-Analyses*) com a intenção de investigar as características clinocorradiográficas das neoplasias malignas linfohematopoiéticas afetando os ossos gnáticos disponíveis na literatura.

4.1 Fontes de dados e estratégia de busca

Para a identificação dos artigos, buscas eletrônicas nas bases de dados PubMed, Web of Science e SCOPUS foram realizadas em julho de 2021. As estratégias de busca utilizadas em cada base de dados estão agrupadas na Tabela 1. As neoplasias de plasmócitos, como o mieloma múltiplo e o plasmocitoma, afetando a região oral e maxilofacial foram excluídos.

As referências recuperadas em cada base de dado foram exportadas para o software EndNote Web. Referências em duplicatas foram removidas após identificação.

Tabela 1 Estratégia de busca utilizada em cada base de dados eletrônica

Base de dados	Ano	Palavras- Chave
Pubmed	2008-2021	(lymphoma OR leukaemia OR leukemia) AND (mandible OR maxilla OR jaw OR gnathic OR "gnathic bones")
Web of Science	2008-2021	(lymphoma OR leukaemia OR leukemia) AND (mandible OR maxilla OR jaw OR gnathic OR "gnathic bones")
Scopus	2008-2021	(lymphoma OR leukaemia OR leukemia) AND (mandible OR maxilla OR jaw OR gnathic OR "gnathic bones")

4.2 Critérios de elegibilidade

Foram considerados elegíveis artigos originais observacionais descritivos, como relato de casos ou série de casos, contendo diagnóstico confirmado de linfomas ou infiltrados leucêmicos em região de maxila e/ou mandíbula. Os artigos

deveriam disponibilizar informações suficientes que tornassem o diagnóstico confiável, como as imagens histológicas ou descrição apropriada dos aspectos histológicos, bem como descrevessem ou apresentassem imagens do painel imunoistoquímico realizado, permitindo determinar a natureza da doença apresentada e a confirmação diagnóstica. A disponibilização de exame radiográfico (radiografia periapical, panorâmica e/ou tomografia computadorizada) e a presença dos dados clínicos individualizados de cada paciente eram fundamentais.

Não foram considerados casos descritos com alterações em outros ossos diferentes de maxila e mandíbula ou que acometeram somente tecidos moles da região maxilo-facial sem alterações ósseas visíveis nos exames de imagem disponibilizados no artigo. Foram também excluídos aqueles casos em que a imagem não estava referenciada ao caso com suas características descritas individualmente. Revisões de literatura, resumos em congresso, pesquisas experimentais, revisões e cartas ao editor não foram consideradas e aqueles artigos cujo texto completo não pôde ser recuperado.

Casos descritos em animais, modelos animais ou cadáveres bem como em outro idioma que não português, inglês ou espanhol também não foram elegíveis para este estudo. Foram buscados artigos a partir de 2008, respeitando-se a data de publicação da quarta edição da classificação de neoplasias hematolinfoides da Organização Mundial da Saúde (SWERDLOW *et al.*, 2008). Um resumo de todos os critérios de inclusão e exclusão pode ser visto na Tabela 2.

Tabela 2 Critérios de inclusão e exclusão dos artigos

	Critérios de inclusão	Critérios de exclusão
Tipo de estudo	Relatos de casos, séries de casos	Cartas ao editor, resumo de congressos, atlas, comentários, revisões
Doença de interesse	Linfomas, leucêmicos	infiltrados Mieloma múltiplo/Plasmocitoma
Localização da doença	Ossos gnáticos (maxila e mandíbula)	Lesões somente em tecido mole, fora do complexo maxilo-facial
Diagnóstico	Painel imunoistoquímico/molecular descrito	-
Exame de imagem	Radiografia panorâmica, computadorizada	periapical, tomografia Somente Magnética, Ressonância PET-scan, ultrassonografia
Linguagem	Inglês, Espanhol, Português	Outros idiomas
Data de publicação	A partir de 2008	Antes de 2008
Participantes	Humanos	Animais

Fonte: Elaborado pelo autor, 2022.

4.3 Seleção dos artigos

Após a remoção dos artigos duplicados, três avaliadores realizaram a leitura do título e resumo de cada artigo selecionado na busca eletrônica. Artigos que trataram do assunto abordado nesta revisão foram selecionados para leitura do texto na íntegra. Uma segunda triagem, avaliando o texto completo dos artigos e a presença de exame de imagem requerido e diagnóstico confirmado por imunoistoquímica foi realizada com a seleção final das publicações para extração de dados. Discordâncias entre os avaliadores durante as duas fases de seleção dos artigos foram resolvidas através de discussão entre os mesmos, até que se chegasse a um consenso. Nos casos em que um ou mais avaliadores discordassem, não havendo consenso entre os três, um quarto avaliador foi consultado.

4.4 Análise da qualidade dos exames radiográficos

Dos artigos com imagens radiográficas coletados, foi realizada uma nova análise e descrição desses exames, a partir da descrição e imagem fornecidas, baseada nos conhecimentos dos avaliadores. Para avaliação da qualidade das imagens disponibilizadas, foi utilizada a classificação descrita por Rodgers *et al.* (2011) que realiza uma modificação da classificação descrita em 1994 pelo *National Radiological Protection Board* (parte do *Health Protection Agency*) que também foi adotado pela *Faculty of General Dental Practice* do Reino Unido e atualizada por esse órgão em 2020 (BRITISH DENTAL ASSOCIATION, 2020; RODGERS *et al.*, 2011). Optou-se pelo uso desta classificação modificada pois ela inclui a categoria “Diagnosticamente comprometido”, que aceita imagens com pequenos erros, mas em que ainda é possível realizar o diagnóstico da área requerida, contribuindo com uma classificação mais objetiva das imagens disponibilizadas. A classificação da qualidade das imagens se encontra descrita na Tabela 3.

Tabela 3 Classificação da qualidade das imagens radiográficas

Classificação	Qualidade	Descrição
1	Excelente	Sem erros no posicionamento e preparação do paciente, exposição, processamento ou disponibilização da imagem.
2	Diagnosticamente aceitável	Alguns pequenos erros no posicionamento e preparação do paciente, exposição, processamento ou disponibilização da imagem, mas que não afetam na utilidade diagnóstica do exame.
3	Diagnosticamente comprometido	Erros mais graves estão presentes e podem comprometer a utilidade diagnóstica do exame, mas a radiografia ainda fornece algum dado diagnóstico, mesmo que limitado.
4	Inaceitável	Erros no posicionamento e preparação do paciente, exposição, processamento ou disponibilização da imagem que tornam o exame inaceitável para o diagnóstico ao qual foi realizado.

Fonte: Elaborado pelo autor, 2022.

4.5 Extração de dados dos artigos

Os dados foram extraídos por três avaliadores e anotados em planilha no Microsoft Excel (2019). As imagens de cada artigo, com seu respectivo diagnóstico, condensadas em um arquivo do Power Point (2019). Discrepâncias durante a extração de dados foram discutidas entre os três revisores até que se chegasse a um consenso e caso necessário, foram discutidos com um quarto avaliador. Foram extraídos dados bibliográficos (autores, ano de publicação, origem), dados demográficos (sexo, idade, localização da lesão), diagnóstico final, dados clínicos (dor, aumento de volume, coloração, necrose, parestesia, dentes acometidos, doença associada, exames imunoistoquímicos/moleculares e envolvimento de outros sítios), dados radiográficos (qualidade da imagem e descrição de cada imagem dos artigos, com densidade radiográfica, localização e alterações ósseas e dentárias).

Foi realizada uma análise descritiva dos dados, utilizando o programa IBM SPSS versão 22.0 e posteriormente uma avaliação analítica dos casos e imagens coletados.

Assunto: Journal of Oral Pathology and Medicine - Decision on Manuscript ID JOPM-09-22-INV-7688

Dear Dr Felipe Fonseca,

It is a pleasure to accept your manuscript entitled "RADIOLOGICAL ASPECTS OF LYMPHOMAS AND LEUKAEMIAS AFFECTING THE JAWS – A SYSTEMATIC REVIEW" in its current form for publication in the Journal of Oral Pathology and Medicine.

Thank you for your fine contribution. We look forward to your continued contributions to the Journal.

The manuscript now becomes the copyright of the Journal. In accordance with accepted practice, the research findings reported in this paper must not appear in another publication before its publication in this Journal.

You are required to complete the standard Copyright Transfer Agreement, the author identified as the formal corresponding author for the paper will receive an email prompting them to login into Author Services; where via the Wiley Author Licensing Service (WALS) they will be able to complete the license agreement on behalf of all authors on the paper.

If you wish your paper to be Open Access you are required to complete the payment form available from our website at: <https://onlinelibrary.wiley.com/onlineOpenOrder>.

Open Access

Open Access is a pay-to-publish service from Wiley-Blackwell that offers authors whose papers are accepted for publication the opportunity to pay up-front for their manuscript to become open access (i.e. free for all to view and download via the Wiley Online Library. Each Open Access article will be subject to a one-off fee of £1525 (equivalent to US\$3000) to be met by or on behalf of the Author in advance of publication. Upon online publication, the article (both full-text and PDF versions) will be available to all for viewing and download free of charge.

Please note that Authors, Editors and Contributors receive a 25% discount on all Wiley books. Just follow the link to register for your book author discount now: <http://www.wiley.com/WileyCDA/Section/id-302237.html>

As part of the Journal's continued commitment to its authors, the publisher wish to keep you informed about what will happen next and, as the attached paper contains information regarding journal publication and services for authors, you may wish to save it for future reference.

We would like to draw your attention to the fact that articles exceeding 8 typeset pages will be charged to the author at a rate of US\$163 per page. When you receive the typeset proofs you will then have the opportunity to reduce the length of the text if the extra page charge poses a problem.

Sincerely,
Professor Peter Brennan
Editor-in-Chief, Journal of Oral Pathology and Medicine

RADIOLOGICAL ASPECTS OF LYMPHOMAS AND LEUKAEMIAS AFFECTING THE JAWS – A SYSTEMATIC REVIEW

Abstract

Background: This systematic review aimed to investigate the radiological features of lymphomas and leukaemias affecting the jaws.

Methods: A systematic literature review was conducted using the electronic databases of PubMed, Web of Science and Scopus. Articles that contained sufficient radiographic examinations (periapical, panoramic or computed tomography (CT) images) for individual cases were included. Additionally, either immunohistochemical or molecular confirmation was required prior to inclusion. Three authors evaluated and described the image quality and radiological features.

Results: From an initial 1079 articles screened, 129 cases were included, containing 88 tomographic, 76 panoramic and 26 periapical examinations. The quality of the majority of images was sufficient for evaluation. Diffuse large B-cell lymphomas (DLBCL), Burkitt lymphoma, leukemic infiltration, plasmablastic lymphoma and extranodal NK/T-cell lymphoma, nasal type (ENKTL, NT) were the most common subtypes. Involved teeth presented with mobility in 37.2% of the cases and a provisional diagnosis of inflammatory/infectious dental disease was considered in 49.2% of cases. CT exams were available for 76% of the cases, with most presented with an osteolytic lesion with ill-defined borders. Periosteal reactions were uncommon.

Conclusion: Lymphoma/leukaemia infiltrates of the jaw bones are usually of high-grade subtypes and rarely present with periosteal reactions.

Keywords: lymphoma, leukaemia, jaw, mandible, maxilla, radiography.

Introduction

Haematolymphoid neoplasms are a heterogeneous group of malignancies that arise from lymphoid cells at different stages of differentiation, manifesting as various subtypes. Leukaemias have an increased number of altered cells in the circulating blood and bone marrow that may infiltrate other subsites. In contrast, lymphomas represent masses of altered lymphocytes in lymph nodes or extra-nodal regions. According to the Global Cancer Observatory (GLOBOCAN/WHO), leukaemia is the 11th highest cause of cancer-related deaths worldwide, with approximately 475,000 new cases registered in 2020. Lymphomas represent the second most common group of malignancies in the head and neck region with around 627,000 new cases registered in the same period.^{1,2} In the oral and maxillofacial (OMF) region, leukemic infiltrations and lymphomas also represent an important group of neoplasms that usually demand a complex diagnostic approach, including thorough clinical work-up, microscopic assessment, and immunohistochemical and molecular analyses.³⁻⁶ In this anatomical region, diffuse large B cell lymphoma, not otherwise specified (DLBCL, NOS) is the most commonly diagnosed haematolymphoid malignancy.³

Considering that from 29% to 48% of all OMF haematolymphoid malignancies demonstrate some form of bone involvement in either jaw bones, understanding the radiological characteristics of these neoplasms may represent useful auxiliary diagnostic tools for clinicians, maxillofacial radiologists, and ultimately oral and maxillofacial pathologists.^{7,8} Additionally, radiological features may be crucial in diagnostic investigation as hematolymphoid neoplasms may resemble a variety of other neoplastic and non-neoplastic conditions including inflammatory and infectious dental-associated diseases. Furthermore, any untimely delay in the recognition and diagnosis of these neoplasms may negatively impact the therapeutic management of affected patients.^{9,10}

Currently, the literature is scarce on describing the most common subtypes and radiological features of haematolymphoid malignancies affecting the OMF region. Therefore,

this study aimed to analyze the clinicoradiological features of malignant haematolymphoid neoplasms affecting the jaws by assessing individual case reports available in the literature following a systematic review approach.

Material and methods

This study followed the Preferred Report Items for Systematic reviews and Meta-Analyses (PRISMA) statement¹¹ intending to investigate the clinic-radiological features of malignant haematolymphoid neoplasms affecting the jaws currently available in the literature.

Search strategy

An electronic search was carried out in July 2021, limited to articles published after 2008, following the publication of the fourth edition of the World Health Organization Classification of Tumors of Hematopoietic and Lymphoid Tissues.⁵ The following electronic databases were assessed: PubMed/MEDLINE, Web of Science, and Scopus. The search strategy used in all databases comprised the following keywords: (lymphoma OR leukaemia OR leukemia) AND (mandible OR maxilla OR jaw OR gnathic OR gnathic bones). Plasma cell neoplasms such as multiple myeloma and plasmacytoma affecting the OMF region were excluded.

Eligibility criteria

Included cases comprised of lymphomas or leukaemias affecting the jaw bones with sufficient clinical, histologic, and immunohistochemical and/or molecular analysis data of each individual case to confirm their diagnoses according to the revised fourth edition of WHO Classification of Tumours of Haematopoietic and Lymphoid Tissues.⁶ Moreover, radiographic examinations [periapical, panoramic, cone-beam computed tomography (CBCT) and/or

computed tomography (CT)] of included cases should be available for retrospective analysis and description. Randomized and controlled clinical trials, cohort studies, cross-sectional studies, case-control studies, case series and case reports published in English, Portuguese or Spanish languages were screened. Lymphoma or leukaemia cases occurring outside the jaws, cases only describing the jaw manifestations of oncologic treatments employed for the patients, publications with insufficient clinical, histologic, and immunohistochemical and/or molecular analysis to render a diagnosis of lymphoma or leukaemia, lesions affecting only soft tissues, and reports using animals, were excluded. Review publications were also excluded, unless they reported cases with sufficient information as part of the review process.

Study selection

Three authors independently screened the titles and abstracts of all articles yielded from the initial search. The studies that fulfilled the inclusion criteria, and those that did not present sufficient information in their title or abstract, were fully assessed. A cross-check assessment of articles was performed by a fourth author to ensure the correctness of included studies, as per the inclusion and exclusion criteria. Duplicate references were initially identified and removed using the EndNote program (EndNote®, Clarivate Analytics, Toronto, Canada), after which a manual review was done to remove other duplicates not initially recognized by the software.

Data extraction

Three authors independently extracted the following data from the included studies: study reference, patients' age, sex, anatomical location and diagnosis of the malignant haematolymphoid neoplasm. Information on clinical signs and symptoms, dental manifestations, initial clinical diagnosis, histopathologic and immunohistochemical/molecular

data for the correctness of final diagnosis were also collected. The same three authors jointly evaluated each of the available radiographic images of the included cases and performed a detailed description. The features analysed included: radiodensity (osteolytic or osteogenic), border definition, dental manifestations/alterations, periosteal reaction, soft tissue involvement and cortical integrity. A cross-check of the radiographic images was performed by a fourth author to ensure accurate and correct imaging descriptions for each examination.

Radiographic quality assessment

The radiographic images included were submitted to a quality assessment based on the modified classification described by Rodgers et al., itself based on the classification of 1994 from the National Radiological Protection Board and the Faculty of General Dental Practice (United Kingdom), updated in 2020.^{12,13} The images were classified into four categories according to their overall quality: excellent (no errors), diagnostically acceptable (minor errors in patient preparation, positioning, exposure, processing or digitalization that does not affect the diagnostic utility), diagnostically compromised (although more serious faults may compromise the diagnosis, the radiograph still yields some diagnostic information) and unacceptable (the image was not suitable for diagnosis). The modified classification includes the “diagnostically compromised” category, which was thought to be of importance in this study. The quality assessment of the images was performed jointly by three authors and cross-checked by a fourth author.

Analysis

Collected data was descriptively analysed using the Statistical Package for Social Sciences (SPSS) software, version 22.0 (IBM Corporation, New York, NY), and the results compiled in the following tables.

Results

Studies selection

The study selection process is summarized in **Figure 1**. The search strategy identified an initial total of 1,627 manuscripts, of which 548 were duplicated and subsequently removed. Of the 1,079 manuscripts screened, 693 were excluded for not being related to the topic, resulting in 386 articles available for full-text screening. Of those, 51 full-text articles could not be retrieved even after contacting the corresponding authors by email and 213 were excluded for not meeting the inclusion criteria. Some manuscripts ($n=104$) did not have radiography and/or CT/CBCT images available for analysis and 3 articles did not present the required data for individual cases ($n=3$). In 48 articles the neoplasm did not affect the jaw bones. Immunohistochemistry was not available in 46 cases to confirm the diagnoses. Finally, 12 manuscripts were excluded because they represented jaw bone manifestations of other diseases in lymphoma/leukemic patients, usually osteonecrosis of the jaw bones. Therefore, a total of 122 studies were included in this review, comprising a total of 129 cases.

Radiograph availability and quality assessment

From the 129 cases included in this study, more than one type of radiographic image (periapical, panoramic and CT/CBCT) was available for analysis in 53 cases. Computed tomography (CT or CBCT) images were available for 88 cases, panoramic radiographs for 77 cases and periapical radiographs for 26 cases. In addition to these imaging modalities, positron

emission tomography/CT (PET/CT) imaging was available in 22 cases, magnetic resonance imaging (MRI) in 19 cases, and a single case utilising ultrasonography. Regarding the different imaging modalities, quality assessment was performed for each image, with 54.6% of the examinations considered excellent, 33.8% were diagnostically acceptable, 11.5% as diagnostically compromised, and none considered unacceptable.

Data description

Demographic data collected from all haematolymphoid neoplasms included in this study are described in **Table 1**. DLBCL was the most common diagnosis (42 cases; 32.6%), followed by Burkitt lymphoma (22 cases; 17.1%), leukaemic infiltrate (19 cases; 14.7%), plasmablastic lymphoma (10 cases; 7.8%) and extranodal NK/T-cell lymphoma, nasal type (ENKTL, NT) (7 cases; 5.4%). There was a male predominance in each subgroup as well as a total male preponderance (82 cases; 64.0%), especially in cases of plasmablastic lymphoma (9:1). The mean age at presentation was significantly lower in Burkitt lymphoma (21 years) compared to the other categories and overall mean age (42 years). Most cases affected adults (98 cases; 77.2%), while infants and adolescents were affected in 22.8% of the cases. There was a similar distribution regarding maxilla (44.2%) and mandible (47.3%), while few cases affected both jaws simultaneously (9 cases; 7.0%). While all subtypes had a similar mandibular/maxillary distribution, ENKTL NT affected only the maxilla. The involvement of other sites, such as bone marrow dissemination or other solid organs, was reported in 38.6% of cases, occurring in more than half of the Burkitt lymphoma and leukaemia cases reported.

Clinical manifestations, dental manifestations and dental treatment reported are described in **Table 2**. The presence of local swelling was the most common manifestation (117 cases; 90.7%), followed by pain in 53.5% of the cases and erythema in 56 cases (43.4%). Paresthesia was reported in 33 cases (25.6%), with three cases defined clinically as presenting

with “numb chin syndrome”. The occurrence of B symptoms, such as fever, night sweats and unintentional weight loss, was present in 22.5% of the cases.

Most of the publications did not report any dental manifestation (58 cases; 45.0%), whereas others reported one or more dental alterations, in most instances tooth mobility (48 cases; 37.2%). Some form of dental pain or tooth/teeth sensitivity on percussion was described in 26 cases (20.2%). Tooth displacement or unerupted teeth related to the lesion were less common (7 cases; 5.4%). Regarding dental treatment, most cases were not treated (66 cases; 52.4%). Tooth extraction (36 cases; 28.6%) and the use of medications (19 cases; 15.1%) were also reported, as well as endodontic therapy (14 cases; 11.1%) or drainage (6 cases; 4.8%) and periodontal treatment (4 cases; 3.2%).

A summary of radiological features of included cases are described in **Table 3**. Regarding the three-dimensional exams, 76.1% of the CT exams included in this study represented multi-slice acquisitions, while 23.9% represented images attained from CBCT imaging. In four of the panoramic examinations, there was no evidence of a lesion. Jaw lymphomas and leukaemias most frequently presented as osteolytic lesions (86.0%) with ill-defined borders (79.1%). Only DLBCL and leukaemic infiltrate presented with an osteogenic appearance. Approximately a third of Burkitt lymphomas and other lymphomas presented with well-defined borders. Effects on the surrounding teeth were uncommon, with 52 cases (40.3%) showing no evidence of tooth alteration, occurring especially in cases of ENKTL, NT and plasmablastic lymphoma.

The most commonly described effect on surrounding teeth included a loss of lamina dura (17.1%), floating tooth/teeth (14.0%) and periodontal space enlargement (12.4%). A periapical lesion appeared in 11.6% of the cases analyzed and some degree of bone loss (9.3%), root resorption (3.9%) and tooth displacement (7.0%) were also reported. Enlargement of the periodontal space and periapical lesions were more common in leukaemic infiltrate, whereas

the so-called floating tooth was more commonly seen in cases of BL. There was no evidence of periosteal reactions seen on any of the available panoramic radiographs. Six cases (4.7%) showed signs of periosteal reactions on CT/CBCT imaging. On CT/CBCT imaging, most cases had some form of soft tissue involvement (81.8%). The disruption of cortical plates was seen in 86.2% of the cases, highlighting the occurrence in all cases of plasmablastic lymphoma analyzed.

Authors of case reports usually provide feedback on the diagnostic work-up of the case, often providing provisional initial diagnoses. Most cases were initially thought to be of inflammatory or infectious origin (63 cases; 49.2%), whereas in 13 cases (10.2%) the clinician considered the lesion to be a malignant process. Four cases (3.1%) were thought to represent an odontogenic cyst or tumour, whereas two cases (1.6%) were described as a reactive hyperplastic lesion. Six cases (4.7%) were described as other diseases on initial clinical examination.

TABLE 1. Summary of demographic data of the lymphoma/leukaemia cases included in this study

Demographic variables N (%)	DLBCL	BL	LI	PL	ENKTL, NT	OL	All cases
Diagnosis N (%)	42 (32.6)	22 (17.1)	19 (14.7)	10 (7.8)	7 (5.4)	29 (22.5)	129 (100)

DLBCL: Diffuse large B-cell lymphoma. BL: Burkitt lymphoma. LI: Leukaemic infiltrate. PL: Plasmablastic lymphoma. ENKTL, NT: Extranodal NK/T-cell lymphoma, nasal type. OL: Other lymphomas.

¹Osteolytic describes radiolucent on periapical or panoramic radiographs and hypodense on CT/CBCT imaging.

²Osteogenic describes radiopaque on periapical or panoramic radiographs and hyperdense on CT/CBCT imaging.

Discussion

Lymphomas and leukaemic infiltration affecting the oral cavity and jaw bones represent an important group of malignant neoplasms usually observed in the gingiva and palate. Although these neoplasms are rare in the jaws, their radiological features may contribute to a final diagnosis.^{3,4} In this study DLBCL was the most common lymphoma affecting the jaws, while Burkitt lymphoma also represented another frequent subtype. Patients affected by this subtype were younger than those affected by DLBCL, consistent with the general epidemiological distribution of lymphomas subtypes in the head and neck region.^{3,14} Leukaemic infiltrations were also reported, mostly in the form of myeloid sarcomas.

We observed that the mandible and maxilla are frequently involved by high-grade lymphoma subtypes, with both being equally affected, as previously reported in the literature (**Figures 2 and 3**).^{3,4,15} Most lymphomas involving the jaws are frequently associated with teeth, either causing tooth displacement, mobility or pain.^{9,16} This presentation can lead to inappropriate dental treatment due to inflammatory conditions, especially when the lesion was located at the tooth root apex. Consequently, dental extractions, endodontic treatments, periodontal therapy and the use of different medications were some of the initial treatment options in these patients, with a resultant negative impact on patients. Therefore, appropriate clinicoradiological correlation with subsequent histopathologic evaluation of lesions that do not follow the expected clinical behaviour are mandatory.

Quality radiographs and CT imaging are mandatory to perform accurate interpretations of the lesions and identify subtle characteristics useful in formulating a differential diagnosis. The study attempted to evaluate if images available in the literature were satisfactory for the readers to perform their own interpretation. The availability, accuracy and detailed description of radiographic examinations in cases of lymphoma/leukaemia in the jaw bones are scarce.¹⁰ We observed that most images available in the literature were considered excellent, but a large

number of articles still presented acceptable or diagnostically compromised images. The most common limitations included image distortions (in acquisition or availability), poor digitalization and resolution, alterations in balance and contrast, and inadequate field of view. With the use of digital imaging modalities, some quality limitations are minimized. However, authors should still be cognizant of the overall quality of images submitted for publication. The radiographic presentation of lymphomas and leukaemias affecting the jaws often varies with many cases resembling reactive/inflammatory dental processes, which may ultimately lead to a misdiagnosis.

In our study, a radiolucent image predominated, with rare examples containing radiopaque foci, likely representing a reactive osseous process or soft tissue enlargement. The only true mixed (radiopaque and radiolucent) lesion present in a periapical image represented a myeloid sarcoma in which the mandibular trabeculae were more radiopaque with areas of patchy radiolucencies.¹⁷ Cases described as radiopaque or mixed in panoramic images represented maxillary sinus opacification.¹⁸⁻²² Radiographic imaging typically revealed a locally destructive pattern, with ill-defined borders and tumour extension to adjacent structures in many instances. This tumour extension often resulted in difficulty establishing the primary location of the neoplasm.²³

The occurrence of periodontal ligament space enlargement is frequently reported in cases of osteosarcoma but may also be observed in cases of lymphoma. Therefore, periodontal ligament space involvement, with or without effacement of the lamina dura, should prompt the clinician to include a haematolymphoid neoplasm in the differential diagnosis. On the contrary, root resorption was uncommon in this study, suggesting that haematolymphoid neoplastic cells likely permeate dental structures rather than causing outright root resorption.^{9,24} Periosteal reactions were also uncommon,²³ and from the six cases in the current study, four represented leukemic infiltrates. The periosteal reactions included a spiculated (or “sunburst”) pattern, with

one case showing a so-called Codman triangle periosteal reaction. These alterations were better demonstrated using CT imaging; however, if CBCT imaging were more used in more studies, the incidence of periosteal reactions may be more prevalent, as it represents a more sensitive technique for dental and jaw bone evaluations. Furthermore, the characteristic floating tooth/teeth pattern usually described in cases of Burkitt lymphoma were also found in other lymphoma subtypes.^{25,26} This feature however was still most commonly seen in BL. Another noteworthy finding was the presence of bone involvement in cases of plasmablastic lymphoma, as recently described by Nel et al.²⁷ who showed a predilection for the posterior region of the maxilla.²⁸ Plasmablastic lymphoma bone involvement presented radiologically with poorly demarcated borders, loss of cortical integrity and cortical erosion or destruction, rather than cortical expansion. These features may be important to differentiate from cases of multiple myeloma, which more commonly manifest as intrabony lesions.²⁹

We found that radiological features alone could not reliably differentiate the lymphoma subtypes. Additionally, literature almost always reported high-grade variants of lymphoma affecting the jawbones. Very rare low-grade lymphoma was reported to involve either the mandible or the maxilla, which paired with other clinical information could assist clinicians in formulating a differential diagnosis. For instance, extranodal NK/T cell lymphoma, nasal type usually presents with mid-palate destruction that cannot be easily observed using a conventional panoramic radiograph. However, this palatine bony destruction is well illustrated using CT imaging and together with its clinical manifestation, may lead to correct clinical diagnosis.¹⁵

In conclusion, it was not possible to find specific radiographic features to differentiate lymphoma subtypes when affecting the jaw bones. We demonstrated that when the jaws are involved by these haematolymphoid malignancies, they usually represent high-grade subtypes, predominantly representing DLBCL, Burkitt lymphoma, T/NK-cells lymphomas, plasmablastic lymphomas, and leukemic infiltrates. Clinicians must be aware that although

uncommon, lymphomas/leukemic infiltrates involving the jaws may also cause periodontal space enlargement and periosteal reactions, and that when closely associated with teeth, radiographic imaging may frequently lead to misdiagnoses. The most common radiological features include an ill-defined osteolytic lesion with frequent reports of cortical disruption. These features are however non-specific which resulted in the presumptive diagnosis simulating an inflammatory process in almost half the cases.

Author contribution statement

All authors substantially contributed with the conception and design, or acquisition of data, or analysis and interpretation of data, have been involved in drafting the manuscript or revising it critically for important intellectual content. All authors have given final approval of the version to be published and each author participated sufficiently in the work to take public responsibility for appropriate portions of the content; and all authors agreed to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved.

5 CONSIDERAÇÕES FINAIS

Os linfomas e leucemias representam um importante grupo de neoplasias malignas que afetam a cavidade oral. Apesar de seu acometimento ósseo ser menos comum, suas características imaginológicas e dados clínicos, podem auxiliar o processo diagnóstico. Neste estudo foi observado que o envolvimento da maxila e mandíbula é mais comum nos subtipos de linfoma de alto grau, podendo se assemelhar a processos de origem dentária, inflamatório ou odontogênico, e levar a um diagnóstico inicial impreciso.

Em geral, as lesões apresentaram um padrão destrutivo, com bordas mal definidas. Não foram identificadas características imaginológicas que permitissem diferenciar os subtipos de linfoma de forma precisa. Os dentes flutuantes (“floating tooth”) considerados característicos do linfoma de Burkitt foram encontrados também em outros subtipos. Os linfomas de células NK/T extranodais tipo nasais são caracterizados pela destruição nasopalatina, que pode ser melhor observada em exames de TC em detrimento às radiografias panorâmicas.

Quando acometem a região das raízes dentárias, os linfomas/leucemias podem se assemelhar à lesões periapicais, doença periodontal ou infecções odontogênicas, causando dor ou mobilidade dental. Estes sinais levam ao tratamento preconizado para essas doenças, que se mostra inappropriado e não responsável, levando ao atraso no diagnóstico da neoplasia. O aspecto radiopaco é raro, geralmente visto como uma opacificação dos seios maxilares ao exame panorâmico, bem como a reação periosteal, melhor visualizada na TCFC. A qualidade dos exames radiográficos para publicações deve ser criteriosamente observada, assim como sua adequada descrição.

ANEXO B – PRISMA checklist

Section and Topic	Item #	Checklist item	Location where item is reported
TITLE			
Title	1	Identify the report as a systematic review.	Page 1
ABSTRACT			
Abstract	2	See the PRISMA 2020 for Abstracts checklist.	Page 3
INTRODUCTION			
Rationale	3	Describe the rationale for the review in the context of existing knowledge.	Page 4
Objectives	4	Provide an explicit statement of the objective(s) or question(s) the review addresses.	Pages 4 and 5
METHODS			
Eligibility criteria	5	Specify the inclusion and exclusion criteria for the review and how studies were grouped for the syntheses.	Pages 5 and 6
Information sources	6	Specify all databases, registers, websites, organisations, reference lists and other sources searched or consulted to identify studies. Specify the date when each source was last searched or consulted.	Page 5
Search strategy	7	Present the full search strategies for all databases, registers and websites, including any filters and limits used.	Page 5
Selection process	8	Specify the methods used to decide whether a study met the inclusion criteria of the review, including how many reviewers screened each record and each report retrieved, whether they worked independently, and if applicable, details of automation tools used in the process.	Page 6
Data collection process	9	Specify the methods used to collect data from reports, including how many reviewers collected data from each report, whether they worked independently, any processes for obtaining or confirming data from study investigators, and if applicable, details of automation tools used in the process.	Pages 6, 7 and figure 1
Data items	10a	List and define all outcomes for which data were sought. Specify whether all results that were compatible with each outcome domain in each study were sought (e.g. for all measures, time points, analyses), and if not, the methods used to decide which results to collect.	Pages 6 and 7
	10b	List and define all other variables for which data were sought (e.g. participant and intervention characteristics, funding sources). Describe any assumptions made about any missing or unclear information.	Pages 6 and 7
Study risk of bias assessment	11	Specify the methods used to assess risk of bias in the included studies, including details of the tool(s) used, how many reviewers assessed each study and whether they worked independently, and if applicable, details of automation tools used in the process.	Page 7
Effect measures	12	Specify for each outcome the effect measure(s) (e.g. risk ratio, mean difference) used in the synthesis or presentation of results.	Pages 6 and 7
Synthesis methods	13a	Describe the processes used to decide which studies were eligible for each synthesis (e.g. tabulating the study intervention characteristics and comparing against the planned groups for each synthesis (item #5)).	Pages 6, 7 and supplementary file 1
	13b	Describe any methods required to prepare the data for presentation or synthesis, such as handling of missing summary statistics, or data conversions.	Page 7

Section and Topic	Item #	Checklist item	Location where item is reported
	13c	Describe any methods used to tabulate or visually display results of individual studies and syntheses.	Pages 6, 7 and supplementary file 1
	13d	Describe any methods used to synthesize results and provide a rationale for the choice(s). If meta-analysis was performed, describe the model(s), method(s) to identify the presence and extent of statistical heterogeneity, and software package(s) used.	Page 7
	13e	Describe any methods used to explore possible causes of heterogeneity among study results (e.g. subgroup analysis, meta-regression).	N/A
	13f	Describe any sensitivity analyses conducted to assess robustness of the synthesized results.	N/A
Reporting bias assessment	14	Describe any methods used to assess risk of bias due to missing results in a synthesis (arising from reporting biases).	Page 7
Certainty assessment	15	Describe any methods used to assess certainty (or confidence) in the body of evidence for an outcome.	Page 7
RESULTS			
Study selection	16a	Describe the results of the search and selection process, from the number of records identified in the search to the number of studies included in the review, ideally using a flow diagram.	Page 8 and figure 1
	16b	Cite studies that might appear to meet the inclusion criteria, but which were excluded, and explain why they were excluded.	Page 8 and figure 1
Study characteristics	17	Cite each included study and present its characteristics.	Supplementary file 1
Risk of bias in studies	18	Present assessments of risk of bias for each included study.	Page 8
Results of individual studies	19	For all outcomes, present, for each study: (a) summary statistics for each group (where appropriate) and (b) an effect estimate and its precision (e.g. confidence/credible interval), ideally using structured tables or plots.	Supplementary file 1 and tables 1, 2 and 3
Results of syntheses	20a	For each synthesis, briefly summarise the characteristics and risk of bias among contributing studies.	Pages 9, 10, 11 and tables 1, 2 and 3
	20b	Present results of all statistical syntheses conducted. If meta-analysis was done, present for each the summary estimate and its precision (e.g. confidence/credible interval) and measures of statistical heterogeneity. If comparing groups, describe the direction of the effect.	N/A
	20c	Present results of all investigations of possible causes of heterogeneity among study results.	Pages 10 and 11
	20d	Present results of all sensitivity analyses conducted to assess the robustness of the synthesized results.	N/A
Reporting biases	21	Present assessments of risk of bias due to missing results (arising from reporting biases) for each synthesis assessed.	Page 8

Section and Topic	Item #	Checklist item	Location where item is reported
Certainty of evidence	22	Present assessments of certainty (or confidence) in the body of evidence for each outcome assessed.	Page 8
DISCUSSION			
Discussion	23a	Provide a general interpretation of the results in the context of other evidence.	Pages 11, 12 and 13
	23b	Discuss any limitations of the evidence included in the review.	Page 12
	23c	Discuss any limitations of the review processes used.	Pages 13 and 14
	23d	Discuss implications of the results for practice, policy, and future research.	Pages 13 and 14
OTHER INFORMATION			
Registration and protocol	24a	Provide registration information for the review, including register name and registration number, or state that the review was not registered.	Not registered
	24b	Indicate where the review protocol can be accessed, or state that a protocol was not prepared.	Available in the manuscript
	24c	Describe and explain any amendments to information provided at registration or in the protocol.	N/A
Support	25	Describe sources of financial or non-financial support for the review, and the role of the funders or sponsors in the review.	Page 2
Competing interests	26	Declare any competing interests of review authors.	Page 2
Availability of data, code and other materials	27	Report which of the following are publicly available and where they can be found: template data collection forms; data extracted from included studies; data used for all analyses; analytic code; any other materials used in the review.	Supplementary file 1
