

Ferns and lycophytes from Serra dos Carajás, an Eastern Amazonian mountain range

Alexandre Salino^{1,4}, André Jardim Arruda^{1,2} & Thaís Elias Almeida³

Abstract

In the state of Pará (Brazil), until the beginning of last decade little was known about the composition of the fern and lycophyte flora. The ferruginous mountains of Carajás are located in Southeastern Pará, mostly inserted in the Floresta Nacional de Carajás. The objective of this work is to present a complete and updated list of fern and lycophyte species occurring in all vegetation types from Carajás ferruginous mountains as a contribution to the knowledge of these plant groups from the Brazilian Amazon. The species list was based on specimens collected between 2007 and 2013. About 1068 specimens deposited in the BHCB Herbarium were studied. A total of 186 species of pteridophytes were recorded, 175 species of ferns distributed in 22 families and 68 genera, and 11 species of lycophytes distributed in three families and four genera. The fern and lycophyte flora of Serra dos Carajás region corresponds to 64% of the Pará state flora of these groups and 34% of the Brazilian Amazon fern and lycophyte flora. Seven taxa are presented as new records for Pará state: *Asplenium abscissum*, *A. otites*, *A. praemorsum*, *Blechnum lanceola*, *Elaphoglossum minutum*, *Doryopteris collina*, and *Hemionitis tomentosa*. Three species are endemic to Serra dos Carajás, *Isoetes cangae*, *I. serracarajensis*, and *Selaginella stomatoloma*.

Key words: Amazonia, canga, FLONA Carajás, floristic, pteridophytes.

Resumo

No estado do Pará (Brasil), até o início da última década pouco se sabia sobre a composição da pteridoflora. As serras ferruginosas de Carajás estão localizadas na região sudeste do Estado, em sua maior parte inseridas na Floresta Nacional de Carajás. O objetivo deste trabalho é apresentar uma listagem completa e atualizada das espécies de samambaias e licófitas ocorrentes em todas as formações vegetacionais das serras ferruginosas da região de Carajás como uma contribuição ao conhecimento da pteridoflora da Amazônia Brasileira. A listagem de espécies foi elaborada com base nos espécimes coletados entre 2007 e 2013 durante expedições botânicas. Foram estudados cerca de 1068 espécimes que estão depositados no herbário BHCB. Foram registradas 175 espécies de samambaias distribuídas em 22 famílias e 68 gêneros, e 11 espécies de licófitas, distribuídas em três famílias e quatro gêneros. A pteridoflora da região de Carajás corresponde a 64% da flora de samambaias e licófitas do Pará e a 34% da pteridoflora da Amazônia Brasileira. Sete táxons são apresentados como novos registros para o estado do Pará: *Asplenium abscissum*, *A. otites*, *A. praemorsum*, *Blechnum lanceola*, *Elaphoglossum minutum*, *Doryopteris collina* e *Hemionitis tomentosa*. Três espécies são endêmicas da região de Carajás, *Isoetes cangae*, *Isoetes serracarajensis* e *Selaginella stomatoloma*.

Palavras-chave: Amazonia, canga, FLONA Carajás, florística, pteridófitas.

Introduction

Currently, 10,578 species of ferns and 1,338 species of lycophytes are recognized (PPG I 2016). In Brazil, according to the Brazilian Flora online, 1,330 species of ferns and lycophytes have been recorded, of which 538 occur in the Amazon and 289 in the state of Pará (Flora do Brasil 2020, under construction).

In the state of Pará, until the beginning of last decade, little was known about the composition of the fern and lycophyte flora, besides the pioneering studies of Huber (1898, 1902, 1906), Sampaio (1930), Cain *et al.* (1956) and Pires (1992). However, from 2003 on, there was a great advance in the knowledge about seedless vascular plants in Pará state due to several floristic and taxonomic studies carried out in forest fragments located around the state capital, Belém (Rodrigues *et al.* 2004; Costa *et al.* 2006; Costa & Pietrobom 2007, 2010; Maciel *et al.* 2007; Ferreira *et al.* 2009; Miranda 2009; Silva 2009), and also in Castanhal (Tavares 2009), Tomé-Açu (Maciel 2008; Maciel & Pietrobom 2010a,b), Portel (Silva & Rosário 2008; Pietrobom *et al.* 2009), Salgado (Costa 2009), Tucuruí (Fernandes *et al.* 2012), Redenção (Fonseca 2010), Monte Alegre (Silva 2010), and in the protected areas of “Calha Norte” (Góes-Neto 2011), as well as new records and other studies (Góes-Neto & Pietrobom 2012a,b; Almeida & Salino 2015; Pallos *et al.* 2016), which have contributed significantly to improve the knowledge on the fern and lycophyte flora in Pará and in the Amazon region.

The Amazon Rainforest is the largest tropical forest on the planet and houses an invaluable biological heritage (Silva *et al.* 2005). Nevertheless, the biome currently has only 80% of its original coverage (Souza Jr. *et al.* 2013), and the creation of protected areas is vital for habitat protection and reduction of deforestation rates. In this context, the Floresta Nacional de Carajás (Flona Carajás) represents an important protected area located in Southeastern Pará and was created with the basic goal of sustainable multiple uses of natural resources and scientific research. Among the mineral wealth found in Flona Carajás, there are extensive ferruginous mountains, which contain one of the largest iron resources on the planet. Together with the mountains of Quadrilátero Ferrífero in Minas Gerais state, these ferruginous outcrops represent 97% of the Brazil's iron reserves (Porto & Silva 1989). Flona Carajás harbors a great variety of vegetation types, from

rainforests to grasslands and savannas, presenting a mosaic associated with various types of soils, rocks, elevations, slopes and microclimates (Cleef & Silva 1994).

The vegetation and flora studies at Serra dos Carajás has begun around 1969 by researchers from the Museu Paraense Emílio Goeldi. The first floristic checklist of the region was published by Secco & Mesquita (1983). According to Viana *et al.* (2016), this work was pioneer and stimulated other floristic studies in the region, and at least five other floristics papers were published between 1986 and 1996. Still, all floristic studies carried out up to that time in Carajás region focused on angiosperms or bryophytes, and only one species of fern was cited by Silva *et al.* (1996).

The fern and lycophyte flora of Serra dos Carajás began to be investigated in 2007 when a group of researchers and collectors associated with the Laboratory of Plant Systematics and BHCB Herbarium from the Universidade Federal de Minas Gerais started to increase sampling of these plants following environmental impact studies at Flona Carajás. From 2009 on there was a considerable increment in fern and lycophyte collections with fieldwork been led by specialists, initially by Thaís Elias Almeida and André Jardim Arruda, and later in 2012 with Alexandre Salino. The largest collection effort was conducted between 2009 and 2013 and generated about 1,000 specimens that are housed at BHCB herbarium. From that collection six new species were described: two *Blechnum* (Dittrich *et al.* 2012), one *Goniopteris* (Salino *et al.* 2014), one *Selaginella* (Valdespino 2015), and two *Isoetes* (Pereira *et al.* 2016).

In 2014 a project entitled “Flora of the *canga* of the Serra dos Carajás, Pará, Brazil” started from a partnership between the Museu Paraense Emílio Goeldi (MPEG) and the Instituto Tecnológico Vale de Desenvolvimento Sustentável (ITVDS), in collaboration with the Universidade Federal de Minas Gerais. From this project, floristic treatments of 22 families of fern and lycophyte occurring at the *canga* in Carajás were published between 2016 to 2018: Aspleniaceae (Moura *et al.* 2016), Cyatheaceae (Salino & Arruda 2016a), Dennstaedtiaceae (Salino & Arruda 2016b), Dryopteridaceae (Moura & Salino 2016a), Lycopodiaceae (Salino & Arruda 2016c), Lygodiaceae (Salino & Arruda 2016d), Oleandraceae (Salino & Arruda 2016e), Pteridaceae (Moura & Salino 2016b), Schizaeaceae (Almeida 2017), Selaginellaceae (Góes-Neto *et al.* 2017).

al. 2016), Thelypteridaceae (Moura *et al.* 2016), Anemiaceae (Pallos *et al.* 2017a), Blechnaceae (Salino *et al.* 2017), Gleicheniaceae (Lima & Salino 2017), Hymenophyllaceae (Pallos *et al.* 2017b), Isoetaceae (Pereira *et al.* 2017), Lindsaeaceae (Pallos *et al.* 2017c), Marattiaceae (Salino & Lima 2017), Nephrolepidaceae (Viveros & Salino 2017a), Polypodiaceae (Almeida *et al.* 2017), Tectariaceae (Viveros & Salino 2017b) and Ophioglossaceae (Salino 2018). These monographs included 70 species occurring in the open vegetation formations of the tops of the hills, known as vegetation associated with *canga* (Viana *et al.* 2016). Despite the high endemism and the importance of these unique habitats in Serra dos Carajás, areas of rainforests mostly associated with slopes and mountain bases present a great variety of microhabitats and consequently a high diversity of vascular plants. For this reason, this work aims to present a complete and updated list of fern and lycophyte species occurring in all vegetation formations at the Carajás ferruginous mountains.

Materials and methods

The Carajás ferruginous mountains are located in Southeastern Pará, 550 km south of the state capital Belém. These mountains are mostly located inside the limits of Flona Carajás and Parque Nacional dos Campos Ferruginosos (Fig. 1), between the valleys of the Tocantins and Xingu rivers (Viana *et al.* 2016). Flona Carajás is in the territory of Parauapebas, Canaã dos Carajás and Água Azul do Norte municipalities (STCP 2003). Parque Nacional dos Campos Ferruginosos is in Canaã dos Carajás and Parauapebas municipalities. The ferruginous outcrops are distributed along different mountains in an extension of 120 by 60 km. The main ranges are Serra Norte, Serra Sul and part of the Serra Leste (Ab'Saber 1986). Together, these mountains represent one of the largest iron resource in Brazil, whose magnitude and economic importance is equivalent to Quadrilátero Ferrífero resource (Porto & Silva 1989). According to Álvares *et al.* (2014), the region climate is Am, presenting a warm and humid moonson tropical climate. The

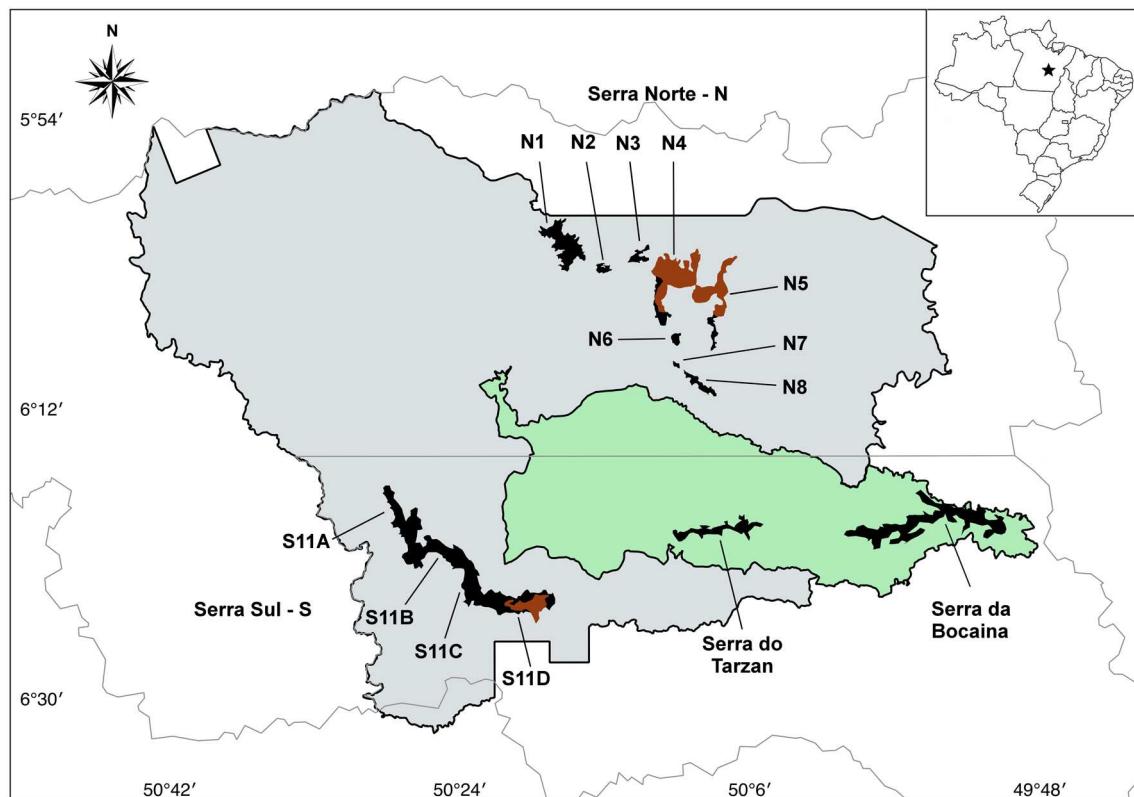

Figure 1 – Study area, indicating the canga plateaus sampled. In black, remaining canga areas; in red, suppressed canga areas (representation based on satellite image taken in December 2016, available on Google Earth). In grey, Floresta Nacional de Carajás. In green, Parque Nacional dos Campos Ferruginosos. Source: Mota *et al.* (2018).

average annual rainfall is of approximately 1600 mm, presenting a rainy season that can reach up to 1300 mm and a dry winter with average less than 320 mm, with the mean of the driest months sometimes reaching less than 60 mm (Moraes *et al.* 2005). The altitude range from 250 m in the foothills to 700 to 800 m in the flattened tops, where the open vegetation types associated with the iron outcrops stand out from the surrounding tropical forest. More detailed information on climate, relief and vegetation in Serra dos Carajás can be found in Mota *et al.* (2015) and Viana *et al.* (2016).

The species list was elaborated based on the collection from BHCB herbarium. Duplicates were sent mainly to the Carajás (HCJS) and the Museu Paraense Emílio Goeldi (MG) herbaria, and also to other herbaria in Brazil and abroad. The checklists contain only one voucher per species. We included in our survey four different ferruginous mountain ranges, of which two are located inside the Flona Carajás (Viana *et al.* 2016): i) Serra Sul (S11A, S11B, S11C, S11D), ii) Serra Norte (N1, N3, N4, N6 and N8); and two are currently included in the Parque Nacional dos Campos Ferruginosos: iii) Serra do Tarzan and iv) Serra da Bocaina (Fig. 1).

Species identification used specialized bibliographies, such as floras, taxonomic reviews, thesis, and dissertations, and as well by comparison with material already determined by specialists deposited in herbaria. When needed, materials and images were sent to specialists for confirmation and/or determination.

Results and discussion

A total of 186 species of pteridophytes were recorded for Serra dos Carajás, which places this study as one of the most representative surveys for the Brazilian Amazon. This number of species (186) corresponds to 64% of the ferns and lycophytes species recorded for Pará (289 spp.) and 34% of the fern and lycophyte flora of the Brazilian Amazon (538 spp.), making Serra dos Carajás one of the most diverse areas in Pará, and Brazilian Amazon.

The most representative families were Pteridaceae (36 spp.), Dryopteridaceae and Polypodiaceae (19 spp. each), Thelypteridaceae (18 spp.), Hymenophyllaceae (16 spp.), Aspleniaceae (13 spp.), Blechnaceae (9 spp.), and Tectariaceae (8 spp.). The expressive richness in families that are predominant in higher areas, such as Blechnaceae and Polypodiaceae, and also of families with known diversity in the Amazon

region such as Pteridaceae, Hymenophyllaceae and Selaginellaceae, corroborate the results obtained in other studies in Pará (Costa *et al.* 2006; Costa & Pietrobom 2007; Maciel *et al.* 2007; Maciel 2008; Fernandes *et al.* 2012). Among the most representative fern genera are *Adiantum* (17 spp.), *Asplenium* (12 spp.), *Trichomanes* (8 spp.), *Blechnum* (7 spp.), *Nephrolepis* (6 spp.), *Cyathea* and *Campyloneurum* (5 spp. each), *Elaphoglossum*, *Microgramma*, *Pteris*, *Triphlophyllum*, and *Tectaria* (4 spp. each) (Tab. 1). The richness observed in *Adiantum* and *Trichomanes* corroborates Tryon & Tryon (1982) remarks that the flora of Brazilian Amazon is well represented by species of those genera. Surprisingly, the richness found for Thelypteridaceae (18 spp.) contrasts greatly with results presented in other studies in the Amazon that do not find this family to be among the most representative ones (e.g., Costa & Pietrobom 2007; Maciel 2008; Costa *et al.* 2006b; Maciel *et al.* 2007; Zuquim *et al.* 2008).

The lycophytes are represented in the area by three families: Isoetaceae (*Isoetes*) with two species, Lycopodiaceae (*Phlegmariurus* and *Palhinhaea*) with two species, and Selaginellaceae (*Selaginella*) with seven species (Tab. 2).

Seven taxa listed here are new records for Pará (Tab. 1, 2). Three species are endemic to Serra de Carajás: *Isoetes cangae*, *Isoetes serracarajensis* and *Selaginella stomatoloma*, and *Goniopteris indusiata* is endemic to Pará.

Regarding life forms, we observed that most species are exclusively terrestrial (70 spp or 37.5%), followed by species sharing rupicolous/terrestrial habit (28 spp. or 15%), exclusively rupicolous (22 spp or 11.8%), epiphytic (18 spp. or 9.7%), and species sharing rupicolous/epiphytic habits (14 spp or 7.5%). Species exclusively hemiepiphytic or aquatic represented only 3.2% (six spp.) and 2.2% (four spp.) of total, respectively. It is also noteworthy that only 35% of the species present more than one habit (65 spp.), while most species (121 spp. or 65%) have an exclusive habit. From the non-terrestrial species with exclusive habit we highlight four aquatic species: *Isoetes cangae*, *I. serracarajensis*, *Ceratopteris pteridoides* and *C. thalictroides*; five hemiepiphytic species: *Polybotrya caudata*, *P. osmundacea*, *Lomariopsis japurensis*, *L. nigropaleata* and *L. prieuriana*; and one climbing species: *Lygodium venustum*.

The low percentage of exclusively epiphytic species found in Carajás (18 spp. or 10%) may be related to the marked presence of savanna

Table 1 – List of families and species of ferns occurring in the ferruginous mountains of Carajás, State of Pará, Brazil, with indication of environments and mountain ranges, life forms and vouchers. Subtitles: Habitat: DRF (dense rainforest); OF (open field); ORF (open rainforest); RV (rock vegetation); SF (swampy field); SFC (seasonal forest on canga). Life form: TE (Terrestrial); EP (Epiphytic); RU (Rupicolous); HE (Hemiepiphytic); AQ (Aquatic). (▲) = new species, (■) = new records for Pará, (♦) = species occurring in the *canga* of Carajás, (◆) = species occurring in the Quadrilátero Ferrífero (MG), (+) = species occurring in the Maçico do Urucum (MS).

Table 2 – List of families and species of lycophytes occurring in the ferruginous mountains of Carajás, state of Pará, Brazil, with indication of environments and mountain ranges, life forms and vouchers. Subtitles: Habitat: DRF (dense rainforest); OF (open field); ORF (open rainforest); PP (permanent pond); RV (rock vegetation), SF (swampy field); SFC (seasonal forest on canga). Life form: TE (Terrestrial); EP (Epiphytic); RU (Rupicolous); HE (Hemiepiphytic); AQ (Aquatic). (**▲**) = new species, (**■**) = new records for Pará, (***■**) = species occurring in the *canga* of Carajás, (**◆**) = species occurring in the Quadrilátero Ferrífero (MG), (**✚**) = species occurring in the Maçico do Urucum (MS).

and grassland formations, which start at 600 m altitude and occupy most of the higher parts of the mountains, thus not favoring the epiphytism due to low density of tree hosts. In addition, a possible predominance of epiphytes that are restricted to the forest canopy, which is generally inaccessible and difficult to observe, may have directly influenced the reduced number of epiphytes recorded.

Regarding the vegetation types, we observed that most species (130 spp. or 70%) were found

exclusively in forest environments. From the 130 species that occurs exclusively in forest environments, 88.5% (115 spp.) occur exclusively in Dense Ombrophilous Forest, followed by 13 (10 %) occurring in Open Ombrophilous Forest. Four species are exclusive from seasonal forest *canga* on the hilltops: *Anemia oblongifolia*, *Campyloneurum centrobrasiliatum*, *Pecluma plumula*, and *Hemionitis tomentosa*. Only 13 species (7%) are unique to non-forest environments.

In addition, three species are exclusive of swampy fields: *Telmatoblechnum serrulatum*, *Acrostichum danaeifolium*, and *Actinostachys subtrijuga*. We also found two species growing exclusively in ponds: *Isoetes cangae* and *Isoetes serracarajensis*, which occurs exclusively in permanent and temporary ponds, respectively.

The occurrence of ferns and lycophytes in Carajás was not uniform. From the 186 recorded species, 153 (82%) occurred at Serra Sul, of which 60 species (32%) recorded only exclusive at this mountain range, followed by 99 species (53%) recorded in Serra Norte, with 16 exclusive species (8.5%); 44 species (23%) recorded in Serra da Bocaina, with only three exclusive species (1.5%); and 37 species (20%) in Serra do Tarzan, with only five exclusive species (2.5%). These values may be biased due to an unbalanced sample effort in these mountains, with bigger sampling effort at Serra Sul and Serra Norte. In Serra do Tarzan, for example, the sampling effort was not exhaustive due to difficulties accessing the most preserved areas. In addition, the mountain ranges differed as to their conservation status. During the sampling period, Serra Sul presented more preserved vegetation formations than Serra da Bocaina that was at the time outside the limits of a protected area and showed bigger anthropic influence in its vegetation.

Along with the mountain ranges of Serra dos Carajás, two other regions in Brazil stand out as the most relevant mountain formations with ferruginous substrate: Quadrilátero Ferrífero (QF) in Minas Gerais state and Maciço do Urucum (MU) in Mato Grosso do Sul state. Salino & Almeida (2008) recorded the occurrence of 380 species of ferns and lycophytes in QF and Assis (2007) recorded 83 species in the MU. From the 186 species recorded in the Carajás region, 65 (35%) also occur in QF and 32 (17%) in MU (Tab. 1, 2).

The surveys and studies focusing on ferns and lycophytes from Serra dos Carajás over the last 12 years revealed a high diversity of species and yielded the discovery of six new species, three ferns (Dittrich *et al.* 2012; Salino *et al.* 2014) and three lycophytes (Valdespino 2015; Pereira *et al.* 2016), as well as three new records for Brazil (Almeida & Salino 2015) and seven new records for Pará state. The knowledge about ferns and lycophytes from Serra dos Carajás contributed to the increase of 31 species known to Pará state. These data reinforce the importance of floristic studies as tools to support and direct conservation policies and emphasize the importance of preserving

ecosystems associated with ferruginous outcrops, not only in the Amazon. Additionally, the high number of taxa and new records for Pará reinforces the existence of collection gaps not only in the state but mainly in the Amazon region (Almeida & Salino 2016).

Acknowledgements

We thank the Graduate Program in Plant Biology of the Universidade Federal de Minas Gerais (UFMG) for general support to the project. Fundação de Amparo à Pesquisa do Estado de Minas Gerais (FAPEMIG) for the Master's degree scholarship to A.J. Arruda. Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) for the research grants to A. Salino (201414/2017-1 and 307115/2017-8) and for the research project financing (455505 / 2014-4). To the project MPEG/ITV/FADESP (01205.000250 / 2014-10). The companies Golder Associates and Vale for supporting the development of the field part of the project. Instituto Chico Mendes de Biodiversidade (ICMBio) for the granting of collecting license and support, especially the biologist Frederico Drumond Martins (Director of the Flona Carajás). To the biologists P.L. Viana, N.F.O. Mota, L.S. Viana, V. Giorni, M. Pivari, F.M. Santos for the samples collections made in the Serra dos Carajás. To the pteridologists V. Dittrich, L. Góes-Neto, J. Costa, R. Viveros, R. Fernandes, F.C. Assis, J. Pereira, L. Sylvestre, D. Sanin and J. Prado for the support in the identification of some taxa.
